

ABOUT LASER THERAPY

Gum disease laser therapy is a minimally invasive treatment that uses a laser to remove infected tissue from the gums and help promote healing. The laser targets bacteria and damaged tissue without affecting healthy areas, making the procedure more comfortable and precise. It is often used for treating gum disease (periodontitis) and helps reduce inflammation, bleeding, and discomfort while encouraging gum tissue to reattach to the tooth. The therapy can also improve overall gum health and reduce the need for traditional surgical methods.

BENEFITS OF LASER IN DENTISTRY

[Dr. Sri](#) is proud to offer the latest technology available for periodontal therapy: laser treatment. There are numerous advantages to using laser therapy as opposed to the traditional methods.

Benefits of Laser in Dentistry:

Comfort:

With laser treatment, there is reduced or no bleeding, minimized swelling, no charring, and no drill noise or vibration. The stress and anxiety often associated with dental work is therefore eliminated when you experience quick, effective, and essentially pain-free laser procedures. Also, postoperative sensitivity is greatly limited by laser dentistry, and recovery time is much quicker than with traditional methods. In fact, due to the less-invasive nature of the laser technique, the mouth begins to heal immediately after work is completed!

Reduced Risk of Infection:

The laser's high-energy light beam acts as a sterilizer on the area it is working, thereby reducing the risk of bacterial infections and relapses.
